Workshop on Parallel Algorithms in Tree Search and Mathematical Optimization

@online

We developed Shortest Vector Problem (SVP) solver using UG

CMAP-LAP: the *Configurable Massive Parallel Solver for Lattice Problem*

- ✓ First Generalized UG application
- ✓ SVP, the combinational problem, supports security of a post-quantum cryptography

Topics of this presentation

- ✓ How to use the Generalized UG to parallelize our solver?
- ✓ Unique new features for solving SVP
- ✓ Show performances of our solver via numerical experiments

1. Contribution & Introduction
2. What is SVP?
3. Key components of parallelization
4. System of our developed solver based on UG
5. Numerical experiments
6. Summary

Topics

1. Definition of Lattice & SVP
2. Features of SVP
3. Benchmark

What is SVP ?

5

Lattice

Definition

An n -dimensional **lattice** is

$$\mathcal{L}(\mathbf{B}) := \left\{ \sum_{i=1}^n x_i \mathbf{b}_i; x_i \in \mathbb{Z} \right\}$$

$\mathbf{B} = (\mathbf{b}_1, \dots, \mathbf{b}_n)$ are linearly independent vectors.
(\mathbf{B} is called a “*lattice basis*”.)

fig: 2-dimensional lattice

All intersection \mathbf{v} in lattice are represented as

$$\mathbf{v} = x_1 \mathbf{b}_1 + x_2 \mathbf{b}_2 \quad (x_1, x_2 \in \mathbb{Z})$$

What is SVP ?

6

Lattice

Definition

An n -dimensional **lattice** is

$$\mathcal{L}(\mathbf{B}) := \left\{ \sum_{i=1}^n x_i \mathbf{b}_i; x_i \in \mathbb{Z} \right\}$$

$\mathbf{B} = (\mathbf{b}_1, \dots, \mathbf{b}_n)$ are linearly independent vectors.
(\mathbf{B} is called a “*lattice basis*”.)

Randomization of lattice basis

$$\mathcal{L}(\mathbf{B}) = \mathcal{L}(\mathbf{UB}) \quad \forall \mathbf{U}: \text{Unimodular matrix} \\ (U \in \mathbb{Z}^{n \times n}, \det(U) = \pm 1)$$

The lattice does not change
by transformation with unimodular matrix

fig: 2-dimensional lattice

All intersection \mathbf{v} in lattice are represented as
 $\mathbf{v} = x_1 \mathbf{b}_1 + x_2 \mathbf{b}_2 \quad (x_1, x_2 \in \mathbb{Z})$

What is SVP ?

7

Shortest Vector Problem

Definition

The **Shortest Vector Problem (SVP)** asks to find the *shortest non-zero vector* in the lattice

$$\begin{array}{ll} \text{minimize} & \|\mathbf{v}\| \\ \text{subject to} & \mathbf{v} \in \mathcal{L}(\mathbf{B}) \setminus \{\mathbf{0}\} \end{array}$$

||

$$\begin{array}{ll} \text{minimize} & \left\| \sum_{i=1}^N x_i \mathbf{b}_i \right\| \\ \text{subject to} & \mathbf{x} \neq \mathbf{0} \end{array}$$

fig: 2-dimensional lattice

What is SVP ?

Shortest Vector Problem

Definition

The **Shortest Vector Problem (SVP)** asks to find the *shortest non-zero vector* in the lattice

$$\begin{array}{ll} \text{minimize} & \|\mathbf{v}\| \\ \text{subject to} & \mathbf{v} \in \mathcal{L}(\mathbf{B}) \setminus \{\mathbf{0}\} \end{array}$$

||

$$\begin{array}{ll} \text{minimize} & \left\| \sum_{i=1}^N x_i \mathbf{b}_i \right\| \\ \mathbf{x} = (x_1, \dots, x_N) \in \mathbb{Z}^N & \\ \text{subject to} & \mathbf{x} \neq \mathbf{0} \end{array}$$

the shortest vector

fig: 2-dimensional lattice

What is SVP ?

Why we try to solve Shortest Vector Problem?

Features

- no single definite algorithm
- SVP supports the security of some lattice-based cryptographies

Lattice-based cryptography

- Common cryptographies have risk to be broken by quantum computers
- **Lattice-based cryptography** is the candidate of new standard post-quantum cryptographies
- urgent to investigate
 - **security level**

IC, credit card ..

If the size of the public key is large, some of the current cryptosystems cannot be replaced new cryptosystem due to memory limitation.

SVP Challenge

- contest of solving **approximate SVP** of 40 – 200 dimension

1.05-approximate SVP

finding $\mathbf{v} \in \mathcal{L}(\mathbf{B}) \setminus \{\mathbf{0}\}$
subject to $\|\mathbf{v}\| \leq 1.05 \lambda_1(\mathcal{L}(\mathbf{B}))$

the estimated optimal value

- Sieve-algorithm solver (G6K) is major, recently

2. Features of algorithms for parallelization

Enumeration (Exactive)

- Depth-first search
- Nodes of the tree correspond to lattice vectors
- Tree contains all lattice vectors with $\text{norm} \leq R$ (parameter)

- ✓ **pros: Low memory usage**
- ✓ **cons: Huge searching time**
 - ✓ $\text{dim } 100 \rightarrow 10^6 \text{ years}$
 - ✓ $\text{dim } 130 \rightarrow 10^{25} \text{ years}$(dim = dimension)

Reduction (Approximate)

- Matrix transformation
- make the lattice basis as close to orthogonal as possible

- ✓ **pros: Low memory usage**
- ✓ **cons: No guarantee for finding the shortest vector**

Sieve (Probabilistic)

- Sampling and Reduce
- Generate shorter vectors by addition(+) and subtraction(-) sampled lattice vectors
- Based on birthday paradox

- ✓ **pros: High performance**
- ✓ **cons: Huge memory usage**

4. Checkpointing

Asynchronously Communication – non-blocking version –

49

Asynchronously Communication – non-blocking version –

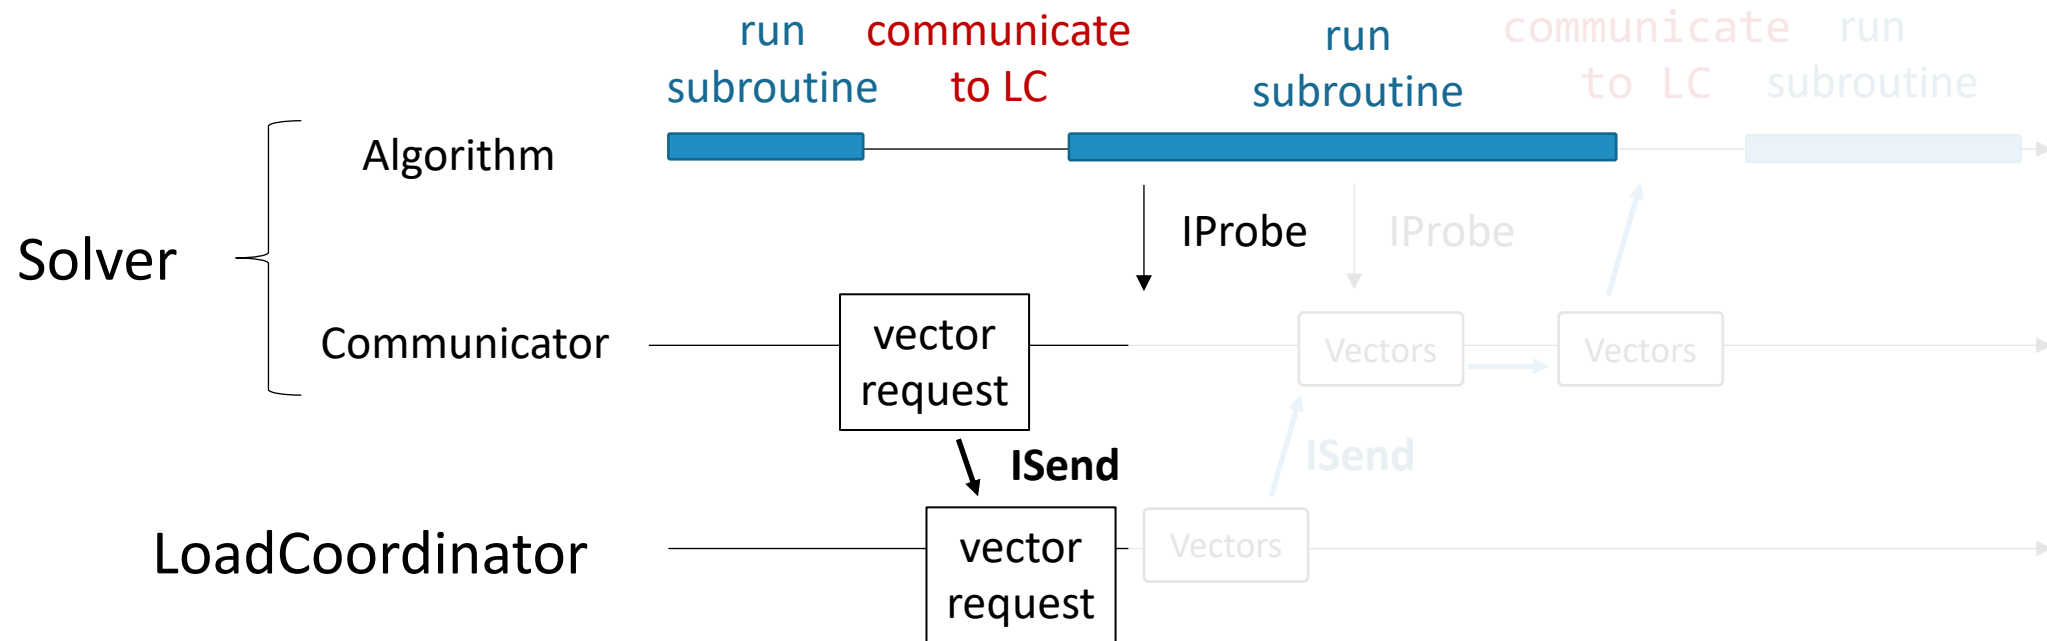

50

- communicator send “vector request” to LC by **ISend** (**MPI_Isend**), which is non-blocking function

Asynchronously Communication – non-blocking version –

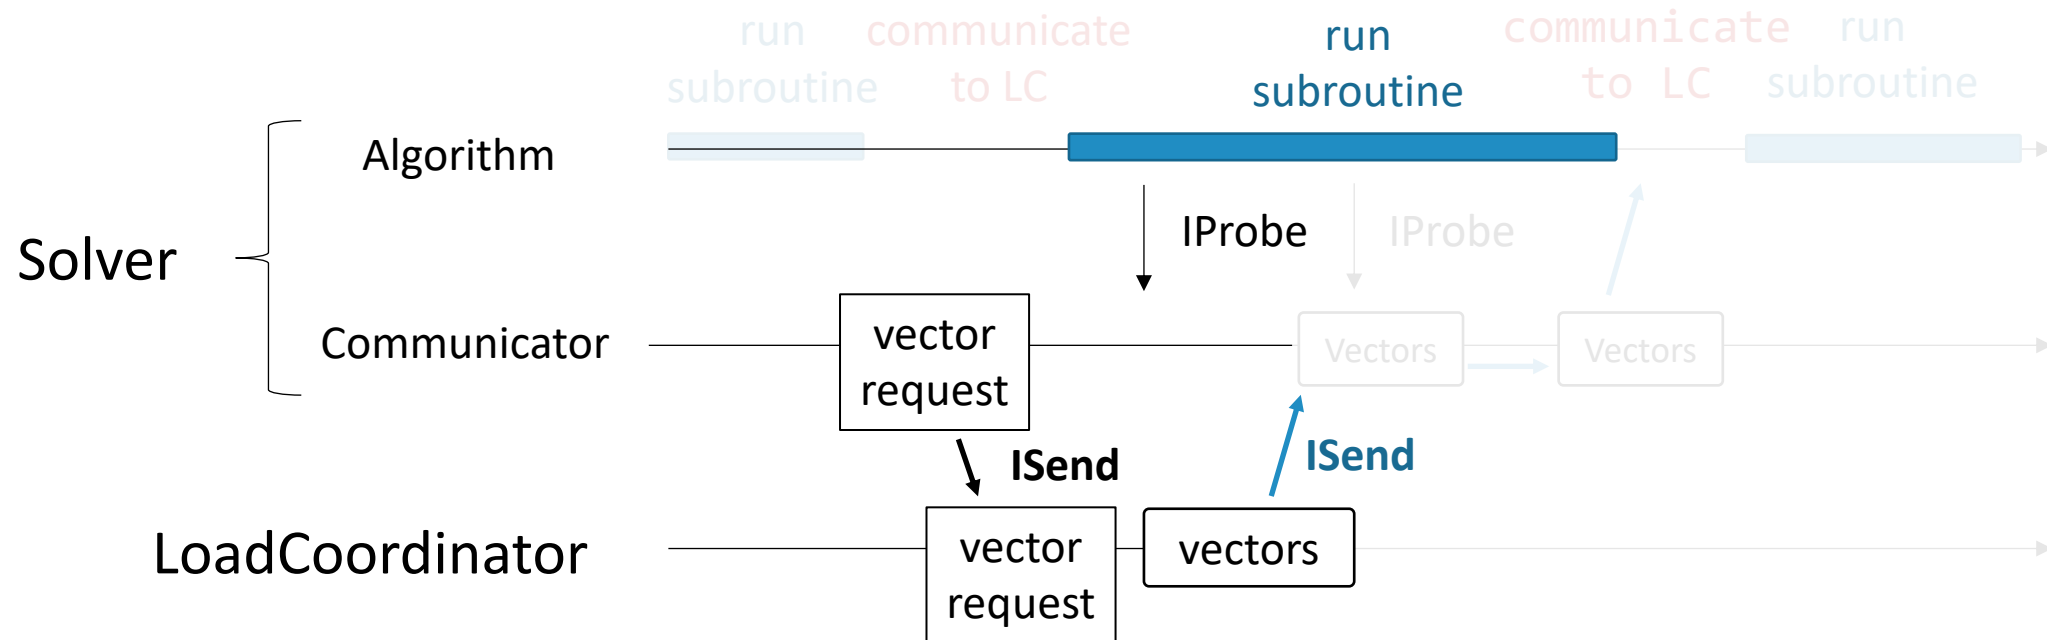

51

- Solver return to running algorithm
- In subroutine, **iProbe (MPI_Iprobe)** is called to check the message

Asynchronously Communication – non-blocking version –

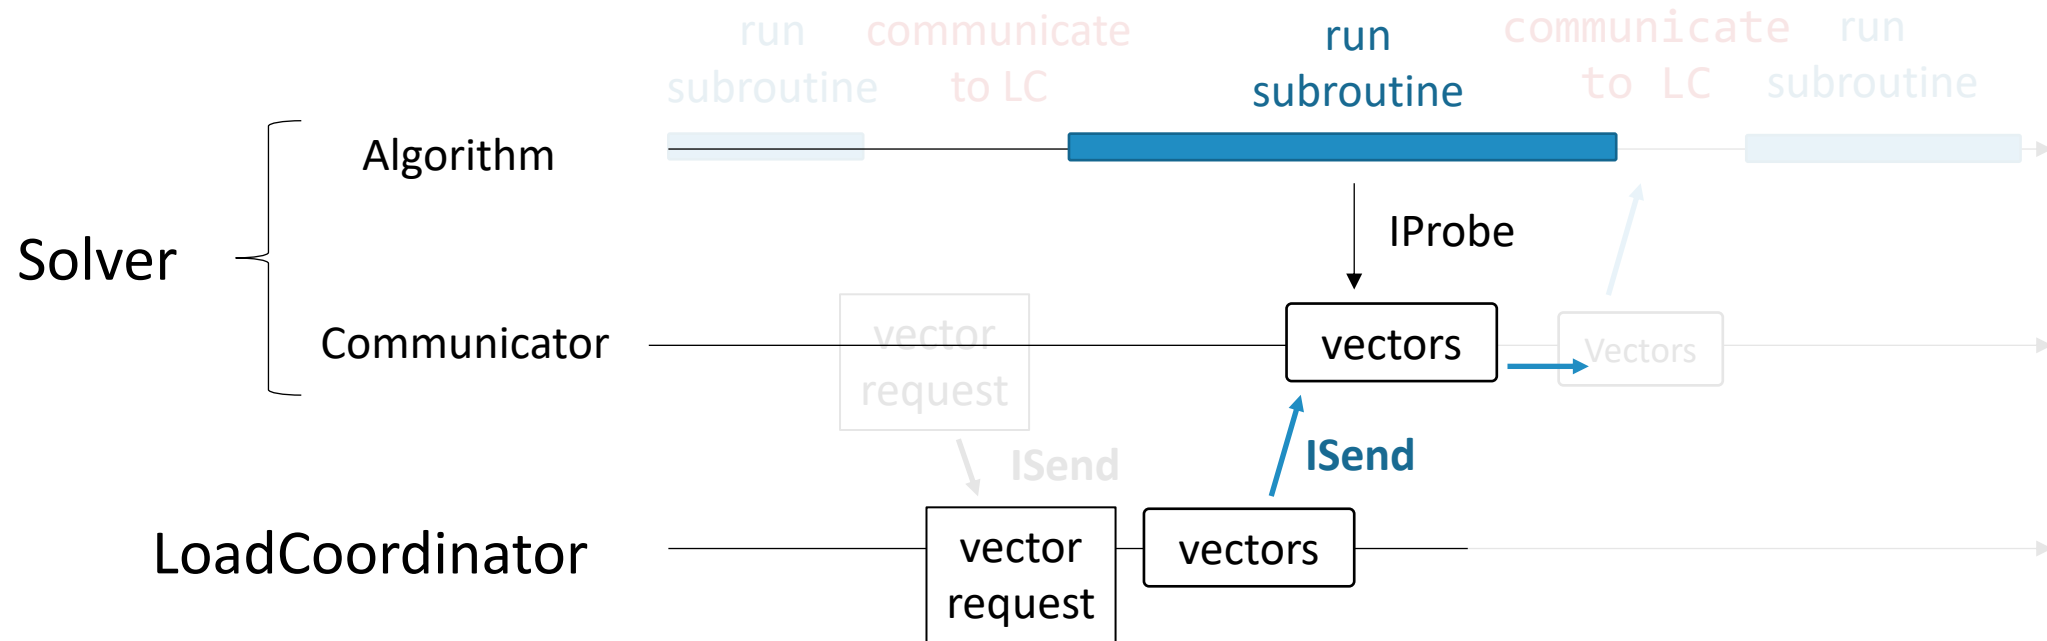

52

- LC prepare vectors according to the vector request
- LC send vectors by **ISend (MPI_Isend)**

Asynchronously Communication – non-blocking version –

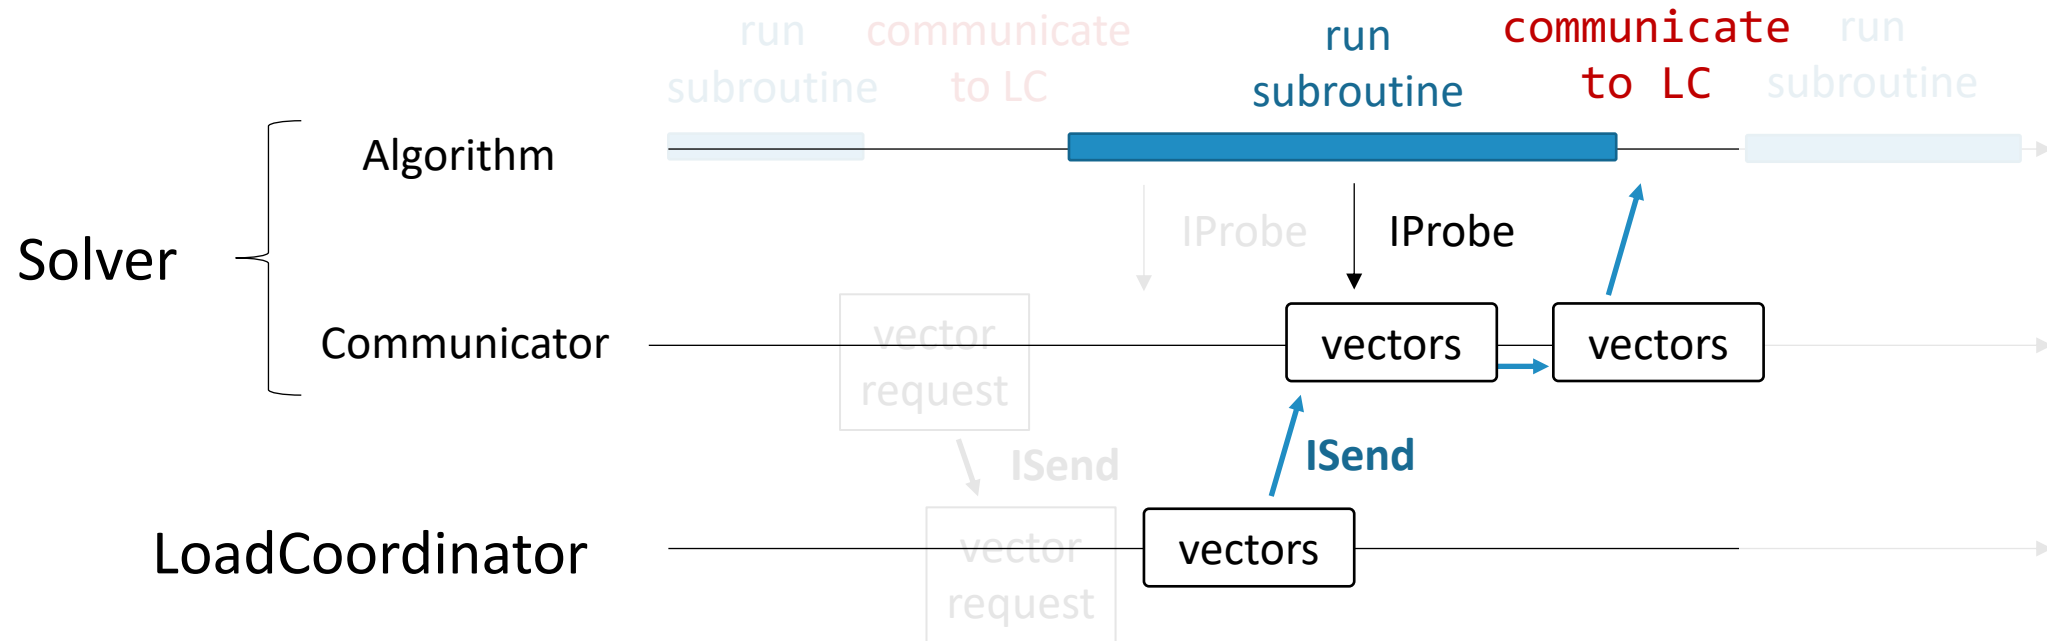

53

- communicator receives vectors and keep them

Asynchronously Communication – non-blocking version –

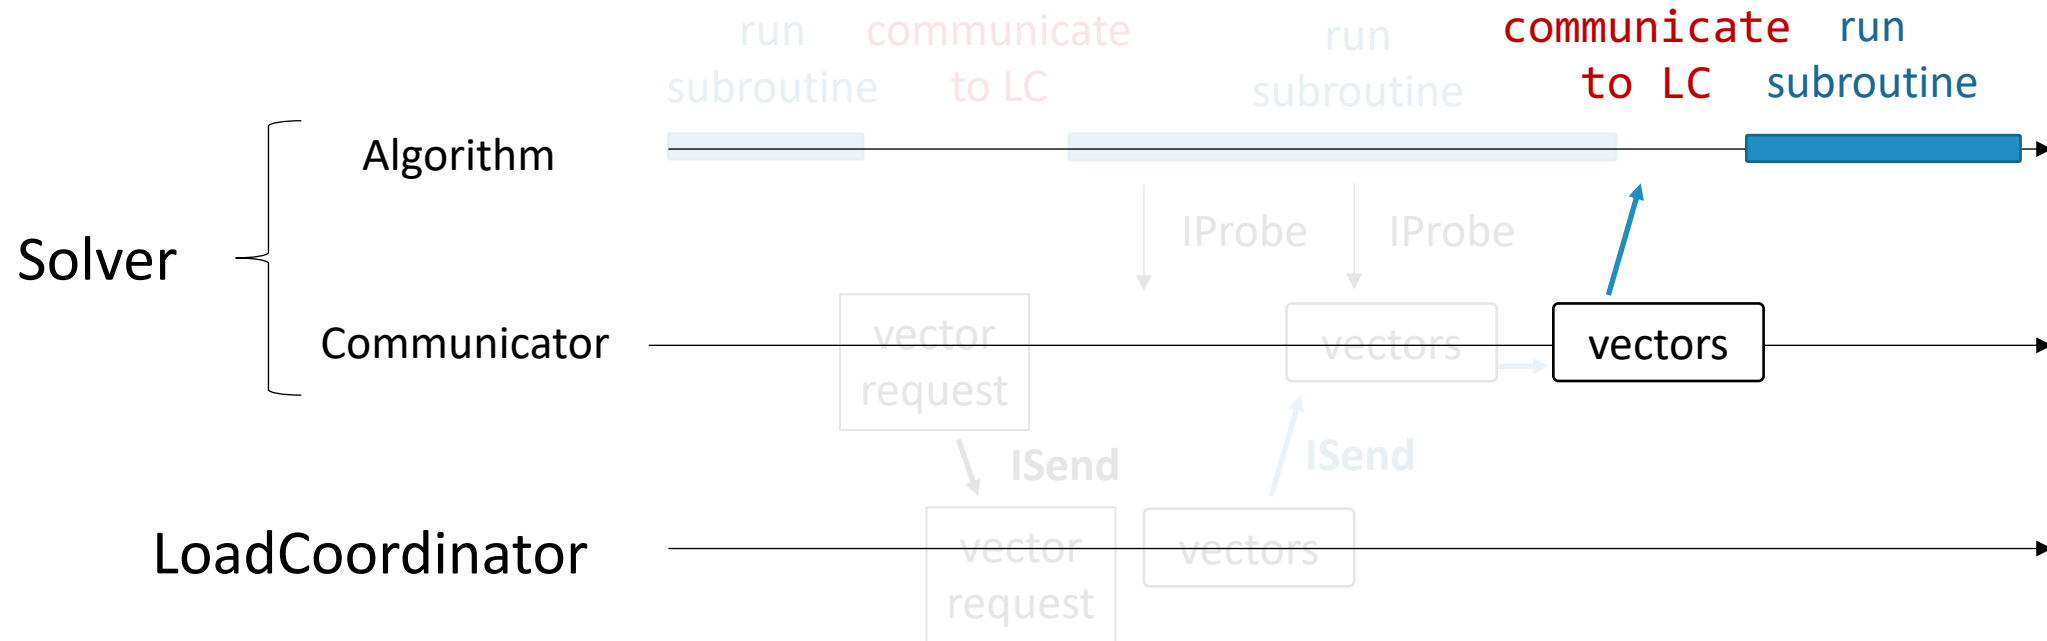

54

- In the following communication part, the algorithm can use the vector received by the communicator

Asynchronously Communication – non-blocking version –

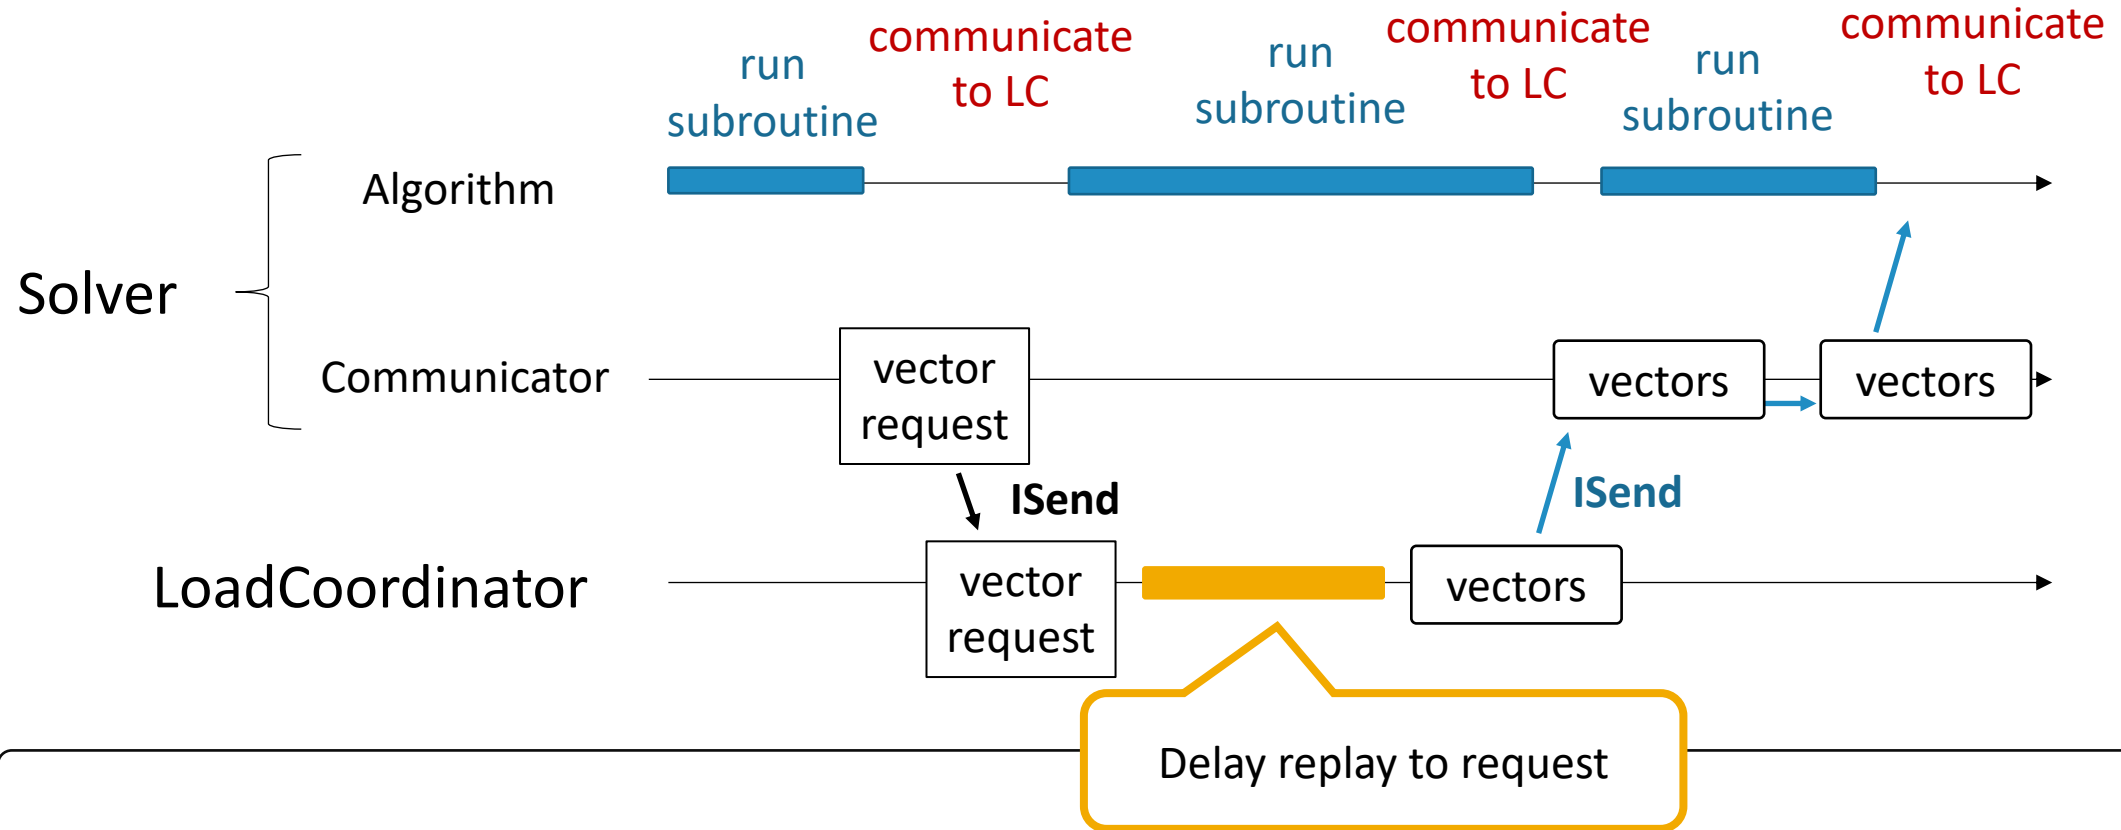

55

- Then, Solver run subroutine again ...

Asynchronously Communication – non-blocking version –

56

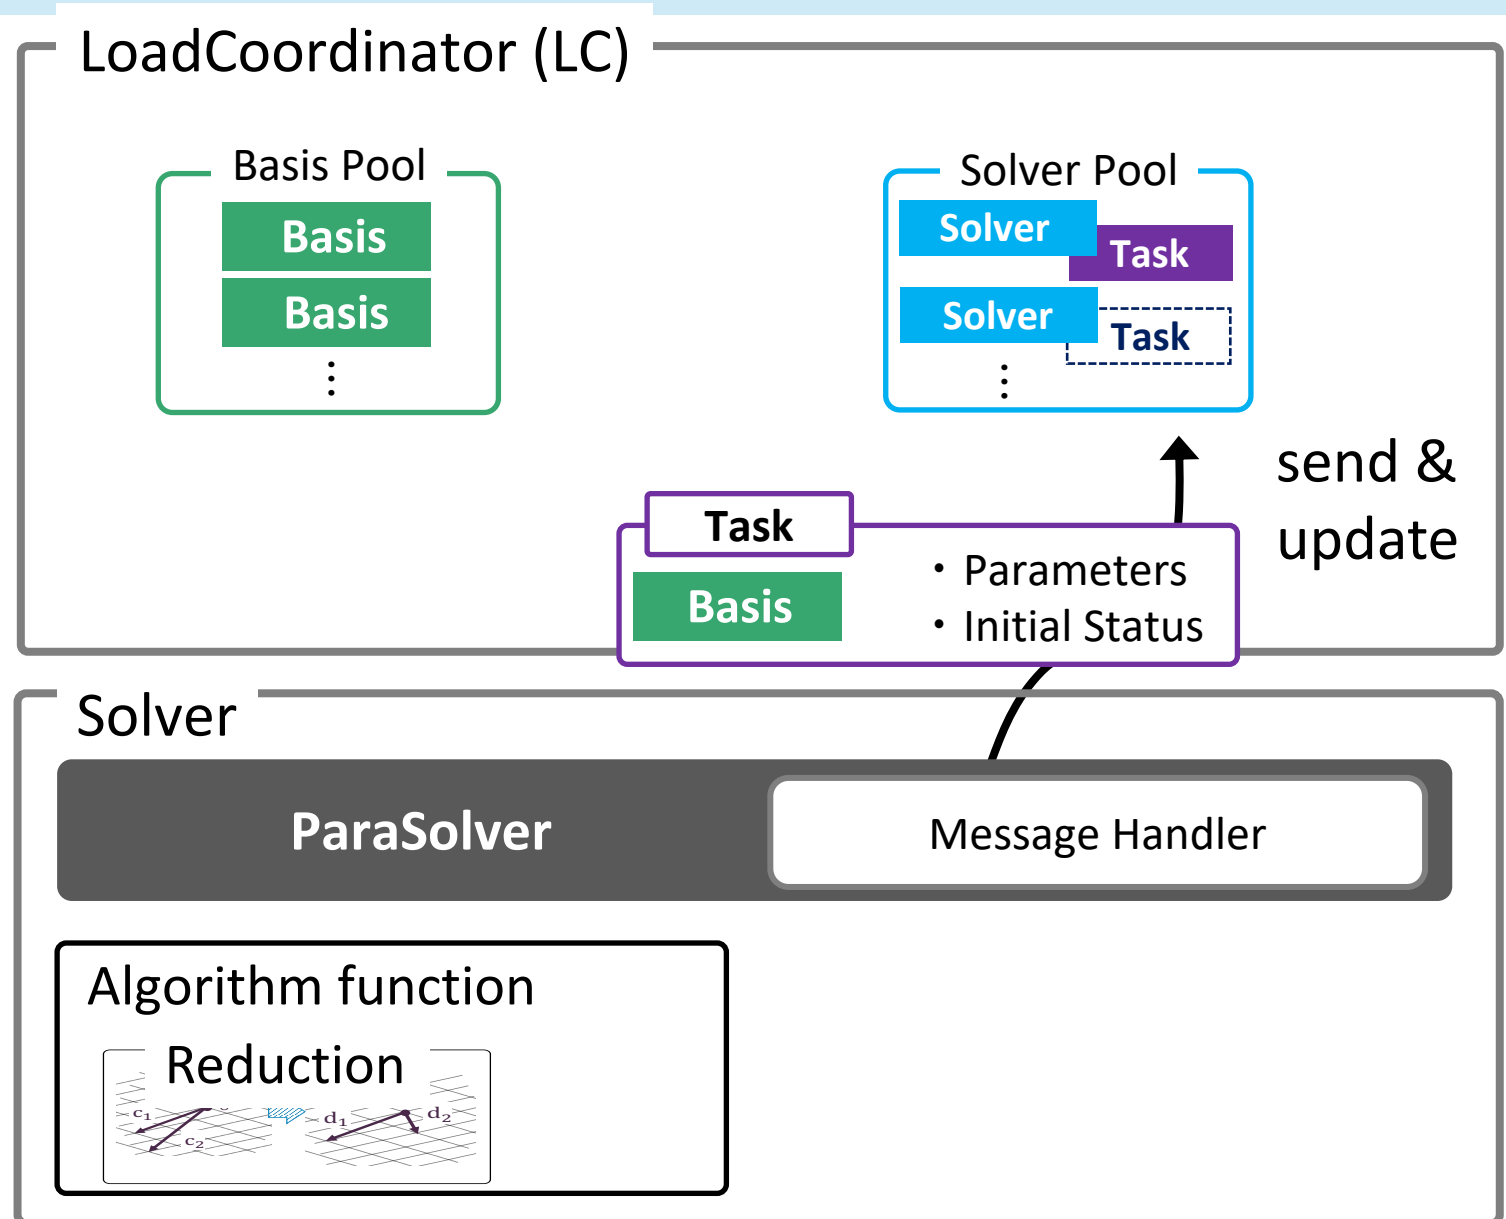

- Even if LC delays in replying to a vector request, algorithm can receive vectors more next communication part
- **SVP algorithm can incorporate vectors at any time**

New solution for SVP Challenge

- CMAP-LAP had succeeded in finding shorter lattice vectors in **104, 111, 121**, and **127** dimensions of the SVP Challenge.
- CMAP-LAP finds a sufficiently short vector in a reasonably short time.
 - The G6K, a famous SVP solver, reported taking **14 days = 336 hours** to find a sufficiently short vector for a 127-dimensional lattice

	2	2809	1.00820	2304	481 minutes
127*	3 [*]	2790	0.97573	91,200	147 hours
	1 [†]	2890	1.01429	9,980	31 hours
	0 [†]	2898	1.01626	49,152	25 hours

*† We executed the CMAP-LAP several times on multiple computers, as described in [3]. Table II shows the results. We list the maximum number of

App. factor := estimated
approximation factor of the
incumbent solution

Scalability

- Scalability keeps even in the larger-scale, e.g., 100,032 processes
- Metric is **Root Hermite Factor** $\gamma^{1/n}$, which is an index to measure the output quality of a reduction algorithm
$$\gamma^{1/n} := \left(\frac{\|\mathbf{b}\|}{\text{vol}(L)^{1/n}} \right)^{1/n}$$
where \mathbf{b} is the shortest basis vector output by reduction algorithm.
- Smaller $\gamma^{1/n}$ means that output quality is good and find shorter vector
- All solver run Reduction (DeepBKZ) algorithm

Sharing efficiency

- Execute with different vector pool size
 - Size of pool = 0 (blue)
⇔ no sharing
 - Size of pool = 1 (orange)
⇔ sharing only incumbent vector
 - Size of pool = 100,000 (green)
⇔ sharing almost all short vectors
- All solver run Reduction (DeepBKZ) algorithm
- With the effect of sharing vectors, the Root Hermite Factor could get smaller

Heterogeneously efficiency

- Execute with different algorithm configuration
- #(Reduction, Enumeration, Sieve)
 - = (143, 0, 0) (blue)
 - = (126, 16, 1) (orange)
 - = (110, 32, 1) (green)
 - = (78, 64, 1) (red)

Heterogeneously efficiency

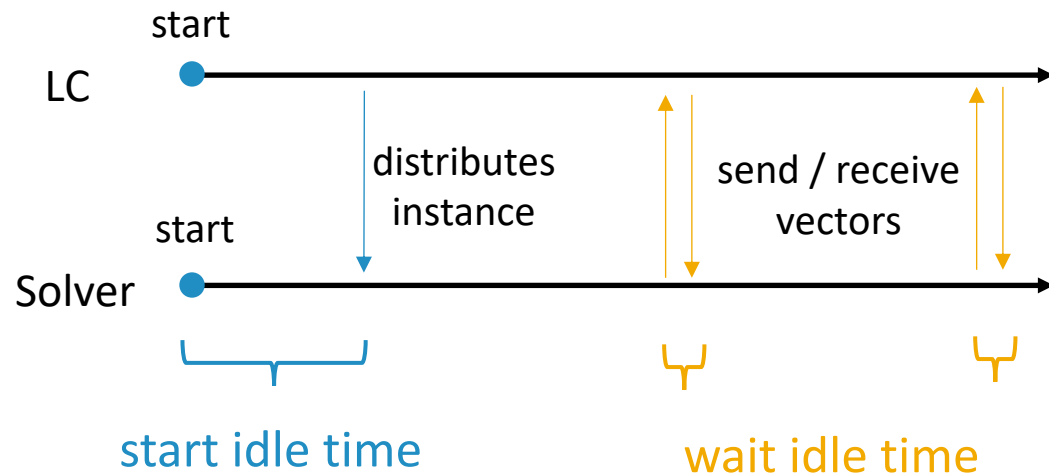

- Execute with different algorithm configuration
- $\#(\text{Reduction, Enumeration, Sieve})$
 - $= (143, 0, 0)$ (blue)
 - $= (126, 16, 1)$ (orange)
 - $= (110, 32, 1)$ (green)
 - $= (78, 64, 1)$ (red)
- There was difference in results depending on the configuration
- For further improvement, it is necessary
 - tuning parameters
 - dynamic modification of the configuration

} Future work

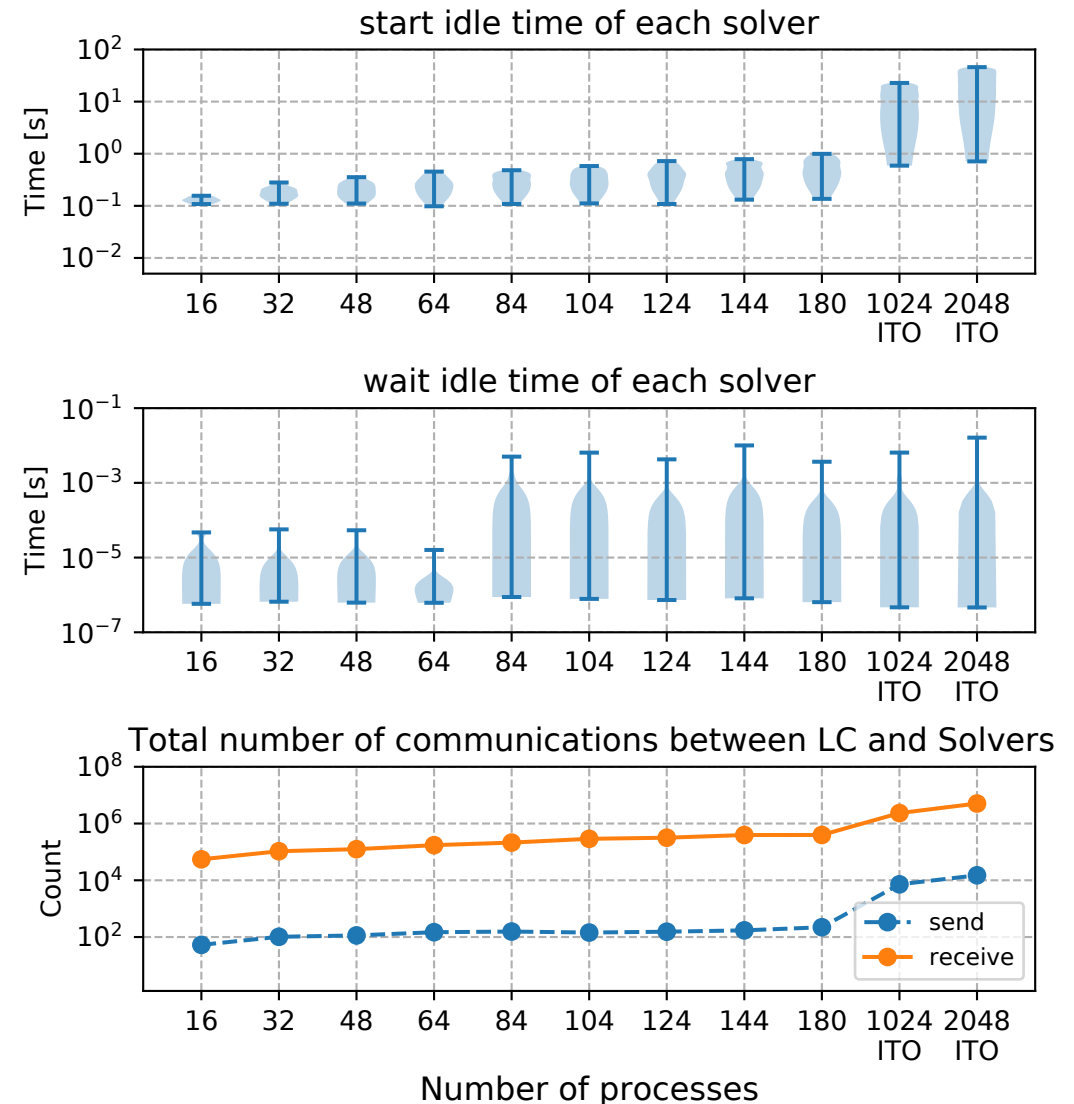

Parallelization performance of UG

- Definition of idle times

Parallelization performance of UG

- CMAP-LAP ran for two hours with 100-dimensional SVP as input
- As the number of processes increases, the LC's load increases
- Although the LC's load increases, idle time is much less than the total running time per hour.

✓ We developed a parallel solver for SVP based on Generalized UG

- ✓ Supervisor-Worker parallelization type
- ✓ Heterogeneous algorithm execution
- ✓ Acceleration by asynchronously sharing lattice vectors

- ✓ Update some SVP Challenge records
- ✓ Show scalability and low communication overhead sharing and heterogeneously efficiency of our solver
